**Epitaxy of 2D Chalcogenides (Epi2DC)**

*External User Publications (Epi2DC)*

The study examined the effect of $^4$He$^+$ ion fluence on the PL and Raman signatures of the irradiated film provides new insights into the type and concentration of defects formed in the MoS$_2$ lattice, which are quantified through ion beam analysis. PL and Raman spectroscopy indicate that point defects are generated without causing disruption to the underlying lattice structure of the 2D films and hence, this technique can prove to be an effective way to achieve defect-mediated control over the opto-electronic properties of MoS$_2$ and other 2D materials. The Materials in this study were synthesized using the 2DCC MOCVD1 instrument.

- External User Project S0041 (National Lab)

This work reveals that thinning silver down to a monolayer leads to the metal transforming to a semiconductor. This work demonstrates that new semiconductors can be formed from transition 2D metals, with the potential for next generation devices for beyond silicon CMOS. The combined capacity of epitaxial graphene growth and advanced characterization, along with Theory at 2DCC-MIP enables this achievement. The materials were synthesized by the 2DCC graphene system and simulations were conducted using the 2DCC computational allocation using ICDS.

This paper reported for the first time the real-time in-operando observation of the degree of crystallographic ordering in a Bi$_2$Se$_3$ film that corresponded to ex-situ assessment of film quality through electronic transport measurements. A precise understanding of the quality of crystal properties of topological insulators and their improvement is crucial to advance the field of quantum materials to harvest their properties in future applications. The 2DCC MBE2 was used to grow the materials and the in-situ SE and RHEED was used to analyze them during growth.

This paper reported the development of a fast optical method to characterize the presence of twin domains in wafer scale films of a 2D van der Waals (vdW) material, alpha-SnSe. This method was exploited to characterize the formation of twin domains during MBE growth of alpha-SnSe films grown on MgO and then used to demonstrate a vast improvement in the crystalline quality of these films by using an appropriate symmetry-matched substrate (a-plane sapphire). The results establish a convenient and rapid methodology for characterizing the structural quality of vdW thin films at the wafer scale. This provides quick feedback to MBE growers seeking to improve the quality of thin films. The materials were synthesized using the 2DCC MBE2 system.

- External User Project R0054 (R1)

This study demonstrates a bottom-up, scalable, and lithography-free approach for creating large areas of localized emitters with high density (∼150 emitters/um²) in a WSe₂ monolayer. This approach of using a metal nanoparticle array to generate a high density of strained quantum emitters will be applied to scalable, tunable, and versatile quantum light sources. WSe₂ use in this study was grown using the 2DCC MOCVD1 equipment.

- External User Project S0065

All-optical graphene modulators reported so far require high pump fluence due to the ultrashort photo-carrier lifetime and limited absorption in graphene. This study presents modulator designs based on graphene-metal hybrid plasmonic metasurfaces with highly enhanced light-graphene interaction in the nanoscale hot spots at pump and probe (signal) wavelengths. The proposed designs hold the promise to address the challenges in the realization of ultrafast all-optical modulators for mid-and far-infrared wavelengths. The 2DCC contributed graphene using faculty equipment.

Molybdenum trioxide (MoO₃), an important transition metal oxide (TMO), has been extensively investigated over the past few decades due to its potential in existing and emerging technologies, including catalysis, energy and data storage, electrochromic devices, and sensors. This study
demonstrates a facile route to obtain wafer-scale monolayer amorphous MoO$_3$ using 2D MoS$_2$ as a starting material, followed by UV–ozone oxidation at a substrate temperature as low as 120 °C. This simple yet effective process yields smooth, continuous, uniform, and stable monolayer oxide with wafer-scale homogeneity, as confirmed by several characterization techniques, including atomic force microscopy, numerous spectroscopy methods, and scanning transmission electron microscopy. The 2DCC contributed materials in this study from MIP equipment MOCVD1.

- External User Project S0047

This study reports a simple, economical, and highly efficient approach for obtaining pristine graphene on a suitable substrate (e.g., SiO$_2$/Si) by utilizing Soxhlet extraction apparatus for delicate removal of the polymer with a freshly distilled ultrapure solvent (acetone) in a continuous fashion. Excellent structural and morphological qualities of the material thus produced were confirmed using optical microscopy, atomic force microscopy, scanning electron microscopy, and Raman spectroscopy. Compared to the conventional protocol, graphene produced by the current approach has a lower residual polymer content, leading to a root mean square roughness of only 1.26 nm. Graphene materials provided in this study were created using non-MIP faculty equipment.

- External User Project R0062 (Non-R1)

In this work, a multidimensional optical imaging technique is developed in order to map subdiffractional distributions for doping and strain and understand the role of those for modulation of the electronic properties of the material. As an example, vertical heterostructures comprised of monolayer graphene and single-layer flakes of transition metal dichalcogenide MoS$_2$ were fabricated and used for biosensing. The 2DCC contributed materials for this study using the MIP equipment MOCVD1.

- External User Project Collaboration between S0016 (Non-R1) and S0034 (Non-R1, MSI/HBCU)

This study presents optical dispersion engineering in a superlattice structure comprising alternating layers of 2D excitonic chalcogenides and dielectric insulators. By carefully designing the unit cell parameters, we demonstrate greater than 90% narrow band absorption in less than 4 nm of active layer excitonic absorber medium at room temperature, concurrently with enhanced photoluminescence in square-centimeter samples. These superlattices show evidence of strong light–matter coupling and exciton–polariton formation with geometry-tuneable coupling
constants. The results demonstrate proof of concept structures with engineered optical properties and pave the way for a broad class of scalable, designer optical metamaterials from atomically thin layers. Materials in this study were provided by the 2DCC using MIP equipment MOCVD1.

- External User Project Collaboration among S0065, S0070 and S0077 (Industry)

Azimuthal reflection high-energy electron diffraction (ARHEED) is demonstrated to be a powerful technique to measure the symmetry, lattice constants, and in-plane orientation domain dispersion in wafer-scale, continuous monolayer WSe2 epitaxially grown by metal organic chemical vapor deposition on c-plane sapphire substrate. The constructed 2D reciprocal map from ARHEED reveals few degrees’ dispersion in WSe2 orientation domains due to the step meandering/bunching/ mosaic of sapphire substrate. Minor 30° orientation domains are also observed. The methodology can be applied to study other TMDCs epitaxial monolayers, graphene, and confined atomically thin hetero-epitaxial metals. Materials in this study were provided by the 2DCC using MIP equipment MOCVD1.

- External User Project S0048

This study unveils the respective roles and impacts of the substrate material, graphene, substrate– graphene interface, and epitaxial material for electrostatic coupling of these materials, which governs cohesive ordering and can lead to single-crystal epitaxy in the overlying film. Results demonstrate that simply coating a graphene layer on wafers does not guarantee successful implementation of remote epitaxy, since atomically precise control of the graphene-coated interface is required and provides key considerations for maximizing the remote electrostatic interaction between the substrate and adatoms. This was enabled by exploring various material systems and processing conditions, and we demonstrate that the rules of remote epitaxy vary significantly depending on the ionicity of material systems as well as the graphene–substrate interface and the epitaxy environment. The 2DCC provided graphene through use of faculty equipment.

- External User Project S0097

This paper reports on the successful growth and modification of monolayer MoS2 (1L MoS2) by controlling carrier concentration and manipulating bandgap in order to improve the efficiency of light emission. Atomic size MoS2 vacancies were created using a Helium Ion Microscope, then the defect sites were doped with 2,3,5,6-tetrafluoro7,7,8,8-tetracyanoquinodimethane (F4TCNQ). The carrier concentration in intrinsic (as-grown) and engineered 1L MoS2 was calculated using Mass Action model. The results are in a good agreement with Raman and photoluminescence spectroscopy as well as Kelvin probe force microscopy characterizations. The 2DCC provided MoS2 materials in this study synthesized by MIP equipment MOCVD1.

In-operando spectroscopic ellipsometry used in this study enabled determining the dielectric function of substrate and growing film unobscured by surface or interface reactions. Its sensitivity to sample temperature and film thickness variations allows determining growth temperature, absolute film thickness, and growth rate in real time, rendering it a reliable and universal approach for a direct comparison of growth conditions between different growth campaigns, thus offering the potential to improve reproducibility of the growth conditions for Bi2Se3 based films and heterostructures. Materials in this study were synthesized using the 2DCC MIP equipment MBE2 and its onboard spectroscopic ellipsometer.

This paper reports on the synthesis of hexagonal boron nitride bulk crystal at room temperature using a single component iron flux which is simpler and more cost effective than current multi-component flux processes. A low nucleation density for WSe2 was observed on the hBN surface indicating a low defect density. The hBN exhibits excellent structural and electrical properties. (WSe2 growth by MIP equipment MOCVD1 was carried out in the 2DCC facility.)

This project explored the use of pump-probe measurements to study the interlayer elastic properties of TMD flakes exfoliated from bulk crystals. Undergraduate students from Vassar College (external user) received training and worked on-site at the 2DCC facility during the summer to synthesize and characterize TMD films which were used during the academic year to carry out the ultrasonic measurements in the lab at Vassar College. Five of the co-authors including the first author are undergraduate students as Vassar.

This study employed x-ray and UV photoelectron spectroscopy to study possible charge transfer between TMD monolayer and gold surfaces and revealed that shifts in the XPS spectra were due
to interactions of defects in the TMD monolayer with the gold surface. Wafer-scale MoS2 monolayers from the 2DCC Thin Films facility were supplied to NRL (external user) for this study.

- External User Project R0024 (National Lab)

This study employed x-ray and UV photoelectron spectroscopy to study possible charge transfer between TMD monolayer and gold surfaces and revealed that shifts in the XPS spectra were due to interactions of defects in the TMD monolayer with the gold surface. Wafer-scale MoS2 monolayers from the 2DCC Thin Films facility were supplied to NRL (external user) for this study.

- External User Project S0048 (non-R1)

Large hexagonal boron nitride crystals were synthesized by solution growth with a temperature gradient. The crystals have low defect density and narrow Raman peak width, providing an alternative method to high-pressure synthesis. Epitaxial growth of TMDs on hBN was carried out in the 2DCC to assess the defect density.

- External User Project S0087

Demonstration of the ability to select different rotational alignments by changing epitaxial growth conditions. This may be used in future wafer-scale growth of hBN/graphene heterostructures to achieve varying degrees of graphene band structure modulation. The project utilized non-MIP equipment to provide epitaxial graphene to external users for hBN growth.

**Local User Publications (Epi2DC)**

Materials composed of nitrogen-doped carbon are useful as catalyst supports due to their low cost, low density, and enhanced metal–support interaction. One way to synthesize catalytic single atoms and nuclei on these supports is via vapor phase deposition processes. Here, density functional theory (DFT) was used to evaluate the effects of N doping and oxidation of graphene on the adsorption and dissociation of trimethyl(methylcyclopentadienyl) platinum (MeCpPtMe3), which is a commonly used precursor in vapor deposition of platinum. DFT calculations confirmed that oxygen incorporation into graphene via oxidation of vacancies is thermodynamically favorable with and without N dopants. The 2DCC contributed DFT using the computational allocation on ICDS.

- Also science driver AdvCM
- Local User Project R0048

This study combines experiment and theory in the 2DCC. The electronic and optical properties of two-dimensional materials can be strongly influenced by defects, some of which can find significant implementations, such as controllable doping, prolonged valley lifetime, and single-photon emissions. In this work it is demonstrated that defects created by remote N2 plasma exposure in single-layer WS2 can induce a distinct low-energy photoluminescence (PL) peak at 1.59 eV, which is in sharp contrast to that caused by remote Ar plasma. The WS2 thin films in this study were grown by 2DCC MOCVD equipment.

*In-house Research Publications (Epi2DC)*

This chapter presents the current status of scalable synthesis techniques for prominent 2D materials, including graphene, transition metal dichalcogenides, and hexagonal boron nitride. Exfoliation methods used to produce large quantities of graphene for inkjet printing are presented. Vapor phase deposition approaches for synthesizing large-scale single-crystalline films are discussed in detail. Critical parameters and their impact on synthesis, such as precursor choice, flux control, and substrate properties, have been examined. 2DCC instruments and faculty instruments are both represented in this summary.

- Collaboration with external user S0069 (National Lab)

This work investigates gas-source metal–organic chemical vapor deposition (MOCVD) of tungsten selenide (WSe₂) on highly crystalline CVD graphene. Single- and multi-layer graphene constitute interesting testing grounds for investigating fundamental WSe₂ growth mechanisms owing to its atomically smooth surface, absence of dangling bonds, chemical inertness, and hexagonal lattice symmetry. Results show how the graphene template properties influence the WSe₂ nucleation site density, growth rate, in-plane orientation, and thickness. WSe₂ growth behavior strongly depends on the number of graphene layers, their stacking order/twisting angle,
as well as on the nature of the substrate underneath. The 2DCC MOCVD1 was used for synthesis of the WSe2 and the Raman on MOCVD was used for characterization.

A combined experimental and theoretical approach was used to investigate the effects of defects, thickness nonuniformities, and chemical functionalization of epitaxial graphene (EG) formed on SiC on Ga intercalation and 2D-GaNx formation to gain insight into this synthesis process. The 2DCC theory computational allocation on ICDS was used for simulation and an existing faculty system was used for materials intercalation.

- Also science driver AdvCM

Novel confinement techniques facilitate the formation of non-layered 2D materials. Here it is demonstrated that the formation and properties of 2D oxides (GaOx, InOx, SnOx) at the epitaxial graphene (EG)/silicon carbide (SiC) interface is dependent on the EG buffer layer properties prior to element intercalation. The study presented here is foundational for development of atomic-scale, vertical 2D/3D heterostructure for applications requiring short transit times, such as GHz and THz devices. Faculty equipment was used for materials intercalation.

- Also science driver AdvCM

Contacting two-dimensional (2D) semiconductors with van der Waals semimetals significantly reduces the contact resistance and Fermi level pinning due to defect-free interfaces. This study examined the evolution of the valence and conduction band edges in pristine and heavily vanadium (0.44%), i.e., p-type, doped epitaxial WSe2 on quasi-freestanding graphene (QFEG) on silicon carbide as a function of thickness. When increasing number of layers the Fermi level of the doped WSe2 gets pinned at the highest dopant level for three or more monolayers. A faculty CVD instrument was used for the materials in this study.

The temperature-dependent desorption behavior of selenium and tellurium is investigated. The direct and quantitative determination of the chalcogen desorption process provides important insights into the kinetics of chalcogenide-based film growth and is in addition of applied benefit to the research community in the area of Se/Te capping and decapping of air sensitive materials as it provides temperature ranges and rates at which full desorption is achieved. The 2DCC MBE2 system was used for growing the materials in this study.
This study analyzes W1-xMoS2 films grown by metal–organic chemical vapor deposition (MOCVD) that have been intentionally grown with various degrees of anisotropy. Because MOCVD allows the controllable introduction of precursors, it is possible to target the growth of predominantly random alloys, as well as alloys with ordering of the metal atoms. Quantification of the atomic positions are presented and connections are made between the atomic structure and the growth conditions. The 2DCC MOCVD1 is use for the synthesis of the materials in this study.

In this work, MoSe2/WSe2 (nanodot/matrix) in-plane heterostructures are synthesized on c-plane sapphire substrates using metal organic chemical vapor deposition (MOCVD) process in order to assess unique light emission properties that arise from spatially confined material. The 2DCC MOCVD1 was used for the synthesis of materials.

Magnetic domains and their corresponding atomic lattice are imaged in monolayer WS2 for a range of vanadium dopant concentrations using Lorentz TEM and atomic-resolution STEM. The material was found to not be uniformly magnetized but contains micron-sized monolayer ferromagnetic domains with an in-plane easy axis and a saturation field of ~50 mT. The 2DCC contributed Theory through use of the computational allocation at ICDS and PARADIM contributed TEM analysis.

- Also science driver AdvCM

The epitaxial growth of wafer-scale semiconducting TMDs monolayers (MoS2, WS2, WSe2) on c-plane sapphire by metalorganic chemical vapor deposition (MOCVD) is demonstrated and the resulting structural and optical properties of the films are compared to elucidate trends based on metal and chalcogen species. The sulfur based TMDs exhibit improved epitaxy, fewer defects and increased photoluminescence intensity on sapphire compared to WSe2 which is attributed to a smaller effective lattice mismatch and improved stability. The 2DCC MOCVD1 instrument is used for synthesis of materials.

This book chapter was contributed based on synthesis techniques used by the 2DCC in-house research team. The chapter discusses challenges in synthesizing high-quality TMDs and provides an overview on the thin-film deposition techniques that show a great potential for making electronic-grade 2D TMD, including powder-based and metal-organic chemical vapor deposition (CVD), as well as molecular beam epitaxy. Second, the chapter discusses several aspects of 2D crystals growth in CVD that would impact the material quality, such as substrates, precursor dissociation dynamics, as well as nucleation and growth kinetics in detail. Lastly, a review of the engineering methods for controlling their heterogeneity through controlling defect type and density, heterostructure formation, and substitutional doping.

Ferroelectric semiconductor field effect transistors can be key enablers to improve energy efficiency and overall chip and memory performance. In this work, low-temperature processed, back-end-of-the-line compatible transistors were demonstrated by depositing a layered chalcogenide ferroelectric semiconductor, beta-phase In₂Se₃, at temperature as low as 400 °C. Top gate n-channel In₂Se₃ thin film transistors were fabricated with field-effect mobility ∼ 1 cm² V⁻¹ s⁻¹, and simple polarization switching based memory results are presented. The In₂Se₃ in this study was grown by a high-pressure chemical vapor deposition (HPCVD) system, faculty equipment.

- External user collaborator S0069 (National Lab)

The structural properties of co-deposited ultrathin PtSe₂ films grown at low temperatures by molecular beam epitaxy on c-plane Al₂O₃ are studied. Postgrowth anneals under a Se flux was found to dramatically improve the crystalline quality of the films. Even before the postgrowth anneal in Se, the crystallinity of PtSe₂ films grown with the co-deposition method was superior to films realized by thermal assisted conversion. Postgrowth annealed films showed Raman modes with narrower peaks and more than twice the intensity. Transmission electron microscopy investigations revealed that the deposited material transitioned to a two-dimensional layered structure only after the postgrowth anneal. PtSe₂ growth was found to start as single layer islands that preferentially nucleated at atomic steps of the substrate and progressed in a layer-by-layer like fashion. Materials in this project were grown by 2DCC equipment MBE2.

Chemical vapor deposition (CVD) of hexagonal boron nitride (hBN) using diborane (B₂H₆) and ammonia (NH₃) is reported. The effect of growth conditions on hBN growth rate using continuous vs. flow modulation epitaxy (FME) method is investigated to gain insight into the role of gas-phase chemistry during film deposition. The results provide additional insight into the effects of gas-phase reactions on CVD of hBN. The 2DCC provided materials in this study from non-MIP faculty equipment.

In this work, subthreshold Boltzmann transport is exploited in complementary 2D field-effect transistors (p-type WSe$_2$ and n-type MoS$_2$) integrated with an analog, nonvolatile, and programmable floating-gate memory stack to develop in-memory computing primitives necessary for energy- and area-efficient hardware acceleration of SA for Ising spin systems. The hardware-realistic numerical simulations further highlight the astounding benefits of SA in accelerating the search for larger spin lattices. MoS$_2$ and WSe$_2$ materials in this study were synthesized using MIP equipment MOCVD1.

A comparison of hexagonal boron nitride (hBN) layers grown by chemical vapor deposition on C-plane (0001) versus A-plane (1120) sapphire (α-Al$_2$O$_3$) substrate is reported. Under the typical growth conditions required for high crystalline quality hBN growth, A-plane sapphire provides a more chemically stable substrate. Materials (hBN) in this study were provided by 2DCC faculty non-MIP equipment and RHEED analysis was contributed using MIP equipment MBE2.

The electron dynamics of atomically thin 2-D polar metal heterostructures, which consisted of a few crystalline metal atomic layers intercalated between hexagonal silicon carbide and graphene grown from the silicon carbide, were studied using nearly degenerate transient absorption spectroscopy. Optical pumping created charge carriers in both the 2-D metals and graphene components. Wavelength-dependent probing suggests that graphene-to-metal carrier transfer occurred on a sub-picosecond time scale. These studies provided insights into electronic carrier dynamics in 2-D crystalline elemental metals, including resolving contributions from specific components of a 2-D metal-containing heterojunction. The correlative ultrafast spectroscopy and nonlinear microscopy results suggest that the energy dissipation rates can be tuned through atomic-level structures. Materials provided by the 2DCC in this study were grown on non-MIP faculty equipment.

Semiconducting two-dimensional (2D) transition metal dichalcogenides (TMDs) are considered a key materials class to scale microelectronics to the ultimate atomic level. The robust quantum properties in TMDs also enable new device concepts that promise to push quantum technologies beyond cryogenic environments. In this Perspective, the authors review some recent results on engineering and probing atomic point defects in 2D TMDs. Furthermore, we provide a personal outlook on the next frontiers in this fast evolving field. Materials included in the 2DCC portion of the analysis were synthesized using non-MIP faculty equipment.

This study discusses newly discovered low-frequency (LF) (<100 cm$^{-1}$) Raman features due to the formation of unique 2D polar metals (Ag, Cu, Pb, Bi, Ga, In) or metal alloys (In$_{x}$Ga$_{1-x}$) intercalated at an epitaxial graphene (EG)/silicon carbide (SiC) interface and demonstrate that 2D-Ag and 2D-Ga can have spatially distinct phases with their own unique Raman responses. Additionally, the study establishes that the 2D-Ga exhibits a structural evolution as a function of temperature, independent of the SiC and EG, that can lead to nucleation of secondary phases. The newly identified LF Raman responses discussed here lay the foundation for rapid, direct, and spatially resolved evaluation of 2D polar metals in ambient. Materials provided by the 2DCC were synthesized using non-MIP faculty equipment.

Patterned polymeric coatings are broadly relevant for all areas of bioengineering: anti-biofouling, controlled protein adsorption, guided cell growth, and many more. This contribution describes a robust topographical and chemical patterning platform that combines an LED digital light projector with oxygen-tolerant light-mediated polymerization to design advanced surfaces on the micron scale and in mild ambient conditions. The user-friendly nature of this approach is targeted towards bringing complex chemical patterning abilities based on surface-tethered polymers into the hands of non-experts and enabling both fundamental and applied studies related to patterned surfaces in bioengineering.

Chemically stable quantum-confined 2D metals are of interest in next-generation nanoscale quantum devices. Bottom-up design and synthesis of such metals could enable the creation of materials with tailored, on-demand, electronic and optical properties for applications that utilize tunable plasmonic coupling, optical nonlinearity, epsilon-near-zero behavior, or wavelength-specific light trapping. In this work, it is demonstrated that the electronic, superconducting, and optical properties of air-stable 2D metals can be controllably tuned by the formation of alloys. Environmentally robust large-area 2D-In$_{x}$Ga$_{1-x}$ alloys are synthesized by Confinement Heteroepitaxy (CHet). Materials in this study were synthesized using non-MIP faculty equipment. Theoretical analysis was provided by 2DCC personnel.

This work investigates the ZnPc physical vapor deposition (PVD) on graphene either as-grown on Cu or as-transferred on various substrates including Si(100), C-plane sapphire, SiO₂/Si, and h-BN. The experiments show that, for identical deposition conditions, ZnPc exhibits various morphologies such as high-aspect-ratio nanowires or a continuous film when changing the substrate supporting graphene. ZnPc morphology is also found to transition from a thin film to a nanowire structure when increasing the number of graphene layers. The observations suggest that substrate-induced changes in graphene affect the adsorption, surface diffusion, and arrangement of ZnPc molecules. This study provides clear guidelines to control MPc crystallinity, morphology, and molecular orientations which drastically influence the (opto)electronic properties. Materials in this study were synthesized using non-MIP faculty equipment.

Engineering atomic-scale defects is crucial for realizing wafer-scale, single-crystalline transition metal dichalcogenide monolayers for electronic devices. Using electron microscopy and ReaxFF reactive force field-based molecular dynamics simulations, this study provides insights into WS₂ crystal growth mechanisms, providing a direct link between synthetic conditions and microstructure. Imaging and ReaxFF simulations uncover two types of translational mismatch, and we discuss their origin related to relatively fast growth rates. Statistical analysis of >1300 facets demonstrates that microstructural features are constructed from nanometer-scale building blocks, describing the system across sub-Ångstrom to micrometer length scales. WS₂ materials in this study were synthesized using MIP equipment MOCVD1 and ReaxFF simulations were conducted by 2DCC personnel.

- Also science driver AdvCM

Scalable substitutional doping of 2D transition metal dichalcogenides is a prerequisite to developing next-generation logic and memory devices based on 2D materials. In this study scalable growth and vanadium (V) doping of 2D WSe₂ at front-end-of-line and back-end-of-line compatible temperatures of 800 and 400 °C, respectively, is reported. A combination of experimental and theoretical studies confirm that vanadium atoms substitutionally replace tungsten in WSe₂, which results in p-type doping via the introduction of discrete defect levels that lie close to the valence band maxima. The p-type nature of the V dopants is further verified by constructed field-effect transistors, where hole conduction becomes dominant with increasing vanadium concentration. Therefore, this study presents a method to precisely control the density of intentionally introduced impurities, which is indispensable in the production of electronic-grade wafer-scale extrinsic 2D semiconductors. Materials in this study were synthesized using non-MIP faculty MOCVD equipment for the doping. Theoretical studies were contributed by 2DCC personnel.

- Also science driver AdvCM

This work focused on the direct and quantitative determination of sticking coefficients of selenium and tellurium which provides important insights into the kinetics of chalcogenide-based film growth and points toward the need of a precise sample temperature control. Results were obtained from materials grown on the 2DCC MIP equipment MBE2.

This paper demonstrated that steps on the sapphire substrate surface can be used to achieve a preferential alignment of WS2 monolayer domains grown by MIP equipment MOCVD1 in the 2DCC facility resulting in a dramatic reduction of anti-phase boundaries coalesced wafer-scale WS2 films. Translational boundaries which result from coalescence of WS2 domains with the same crystallographic direction, but sub-unit cell offsets were observed to be the predominant line defect in the films. The optical and transport properties of the MOCVD-grown TMD monolayers were comparable to that reported for exfoliated flakes.

This review article summarizes recent breakthroughs in low-temperature synthesis for TMDs for semiconductor applications. It is the first review of its kind.

The study demonstrates a viable approach to introducing dopant-level impurities with high precision, specifically focusing on Re as the dopant atom, which can be scaled up to batch production for applications beyond digital electronics. The MIP provided support for both theory and experiment.

- Also Science Driver AdvCM

This work identified a new type of structural defect – metal vacancy arrays – which form in epitaxial WS2 monolayers grown by MOCVD due to coalescence of domains that are slightly offset from one another. This study was a collaboration between 2DCC personnel in the Thin Films and In Situ Characterization Facility and the Theory/Simulation working on epitaxial growth of TMDs, advanced electron microscopy characterization and theory and simulation.
